TITLE: Comparison of the methods of harmonic analysis of tidal measurements by Pertsev and Venedikov

SOURCE: Studia geophysica et geodaetica, v. 9, no. 3, 1965, 230-235

TOPIC TAGS: harmonic analysis, ocean tide, gravimeter, oceanographic equipment

ABSTRACT: A comparison was made of the two methods by using material from the Pribram-Brezove Hore tidal station, shaft "Anna" (observations with horizontal pendulums) and the Sofia station (observations with the Askania gravimeter). On the basis of the comparatively small number of comparisons made, the two methods appear to be practically equivalent in the given case. Orig. art. has 4 tables.

TITLE: Use of non-tidal effects from records of tidal observations in studying recent crustal movements.

SOURCE: Studia geophysica et geodaetica, v. 10, no. 1, 1966, 101-105

TOPIC TAGS: ocean tide, earth crust

ABSTRACT: The article presents the results of an analysis of selected non-tidal effects from the records of Czechoslovak tiltmetric stations and points out the need to pay much greater attention to their investigation in connection with the study of crustal movements. [JPHC]

TITLE: Topographic gravity corrections for the territory of Czechoslovakia

PERIODICAL: Referativnyy zhurnal, astronomiya i geodesiya, no. 6, 1961, p. 1 abstract 66185 ('Geofiz. zh.', 1961, no. 129 - 130, 1961). (Czech; Russian and English summaries)

TEXT: A team of the gravimetric department of the Geophysical Institute of the Czechoslovakian Academy of Sciences has compiled, as a result of hydrographic work, a 1:200,000 map for the entire territory of the republic for calculating gravity corrections. Corrections are introduced, with an accuracy of +/- 26... for the relief within the Hayford zone C for intensity 2.67. Separate sheets of the map are presented for mountainous, hilly and plain regions. Isolines of equal correction values are drawn through 0.2 mgal. The Earth's curvature is taken into account. The values obtained from the map should be added with a correction determined from the appended nomogram for the height of the points and a correction, calculated for every point, for the effect of relief masses within a radius

Card 1/4

T-topographic gravity corrections...

of 5.1 mgal. The isobogram line is a part of the relief profile, which is statistically determined, varying regularly with the height. The value of the profile is chosen so that corrections indicated in the map should be independent of the point heights. A sheet of the 1:100,000 map is taken for the correction. Maximum values on the maps are 1.5 mgal. Topographic and hypsometric corrections from scale 1:100,000 are used for the elevations. Corrections are made for special points of the relief indicated on the maps. About 40 points are fixed on each sheet of the 1:100,000 map; in mountains - sometimes up to 100. Calculated values are presented on the maps. The effect of elevation is determined for four points on the 1:100,000 sheet, and that of the section for one point. For each quarter of the sheet calculated a graph of the difference between the lines $M - G_2$ in the point height is plotted, and this effect is introduced into all points of the section. Graphs of adjacent sections determine the effect between the lines $M - G_2$ with a difference of, in most cases, ~0.6 mgal. In high-mountainous regions of Slovakia the sections are reduced. If any dependence of coefficients of quantities presented on the map on relief heights was noticed, the heights of locality were taken into account while drawing the isolines. For the control, corrections for relief were calculated for 207 points uniformly distributed.

Part I: Topographic gravit. corrections...
determining the influence of zones M - H ... estimated by the author. The method is given. This suppose that errors of influence of zones I - G₂ are not dependent on mean height. The mean error of this influence is estimated to be 0.001 mgal. A correction is presented for Bullard's term; a difference of effects on gravit. between a spherical layer within the external radius of Hayford C zone and infinite layer of the same thickness. For zones H - G₂ a correction table is given for sections of zones and subzones B - H on corrections for relief (up to 0.001 mgal). It is shown in tables, which accuracy is required for mean heights in these sections, subzones for calculating their effect with an accuracy of 0.1 and 0.3 mgal at mean elevations close to zero and 100 m. It is shown also, what an accuracy is required for determining mean heights in sections of zones I - G₂ for calculating their effect with an accuracy of 0.1, 0.2, 0.3 and 0.4 mgal at mean elevations of locality 500, 1,000, 1,500 and 2,000 m. A map of topographic corrections for zones '8 - 1 of Hayford for Czechoslovakia is presented. A map of topographic isostatic reductions of these zones has been prepared. For 14 points, uniformly distributed over the land territory, the table gives effects of topographic

Card 3/4

Topographic gravity corrections...

3/035/62/reduced

masses in zones 18 - 14, 13 - 10, 9 - 8 and 7 - 1. The effect of zones changes most considerably (up to 3 mgal) and rapidly. Tables are given for normal gravity values according to Gel'mert formula 1901 - 1909 in the range $47^{\circ}30'$ to $51^{\circ}50'$ in intervals of $10'$ in latitude; the tables contain also reductions in free air for heights from 0 to 1,000 m in intervals of 1 m of height, with an accuracy of ± 0.01 mgal and from 1,000 to 2,700 m in intervals of 100 m with an accuracy of ± 0.1 mgal, additional corrections to these reductions for Bouguer's term (with the same height intervals and accuracy as in the tables of reductions for free air) for conversion from the assumed value of density to other value. There are 16 references.

AUTHOR: Picha, Jan

TITLE: Comparison of methods for harmonic analysis and some comments on the controls of the calculations

PERIODICAL: Studia geoph. et geod., no. 1, 1960, 85-94

TITLE: This paper is the reprint of a report read by the author on the 3rd International Conference on the Earth Tides at Triest in July 1959. Within the scope of the IGY, the Gravimetric Division of the Geophysical Institute, CAS, established a second tide station on the 36th sole of the "Anna" mine at Březové Hory (Příbram), 1,300 m below the surface, at 772 m above the mean sea level. This station has been equipped with a Schweydar device with 2 simple horizontal pendulums and a photographic recorder. The Doodson-Lennon, Lecolazet, and Pertsev methods of harmonic analysis were applied to the observation material and compared. The purpose of this paper is the determination of how the results differ from each other. The author found out that the methods do not differ greatly. Reviewer: A. Zátopek. There are 2 figures, 9 tables and 6 references.

AUTHOR: Kolokolov, V. P.; Pichakhchi, G. I.

TITLE: The level of atmospheric interference and certain peculiarities of thunderstorm activity

SOURCE: Leningrad. Glavn. geofiz. observatoriya. Trudy*, no. 146, 1963. Atmosfernoye elektrичество, 21-27

TOPIC TAGS: atmospheric interference, atmospheric electricity, thunderstorm, thunderstorm activity, lightning, lightning discharge, atmospheric discharge, storm recording device, storm duration, meteorology

ABSTRACT: An attempt was made to find a correlation between the intensity of atmospheric interference (the number of lightning discharges) and the climatological characteristics of thunderstorm activity. An attempt was also made to establish relations among these climatic characteristics as they are observed over an extensive territory. The solution of the first part of the problem involved in question: with what climatological characteristics can atmospheric interference be most conveniently compared? At first, the authors compared the number of lightning discharges, recorded by a PRG-1 storm recording device, with

Card 1/4

ACCESSION NR: AT4011511

climatological characteristics, finding, in this way, the values of the correlation factors between the sum monthly number of discharges recorded by the device (threshold of sensitivity: 1.5 v; approximate effective radius: 20 km; passband: 6 kc; frequency band: 60-66 kc) on the one hand and the sum monthly number of days with storms and the sum monthly duration of the storms in hours on the other hand (for Tbilisi and Sverdlovsk, summer season, 1960). As atmospheric interference characteristics, the authors used material on the number of the atmospheric discharges recorded during the summer season of 1961 at Sverdlovsk, Odessa and Leningrad. This recording was made with a PRG-1, with the sole difference that this device was more sensitive and had a broader band (2-20 kc). It soon became apparent that, for the authors' purposes, a climatological characteristic such as the sum duration of the storms (in hours) was most convenient. The authors qualify a certain part of the conclusions by stating that their results pertain to atmospherics which give rise to large field intensities and which, consequently, are generated by nearby thunderstorms. With regard to atmospherics of low threshold values (below 100 millivolts/meter, for example), these may arrive from great distances, exceeding the delimitations of the territory selected. Moreover, the level of these atmospherics will, to a considerable degree, depend on superlongwave propagation conditions; that is, on the state of the ionosphere. The authors discovered, in

Card 2/4

ACCESSION NR: AT401151!

general, the maximum sum duration of thunder storms in elevated and adjacent regions. There is, naturally, a tendency toward an increase in the level of atmospheric interference as the latitude of the observation point decreases. However, there are local regions which constitute exceptions to this general law. It should also be noted that in regions with a large percentage of stormy days, or with a large number of storms, the storms themselves are, on the average, of greater duration. In this connection, however, it is interesting to note that there is no correlation between the number of thundersstorms and their mean duration (see Fig. 1 of the Enclosure). It may be assumed, the authors claim, that the plotting of storm duration charts would be useful for an estimation of the number of electrical discharges per unit area, provided the proper reference readings are taken at several points within the European Territory of the USSR. Causes of flake formation in billets of chromium-nickel-molybdenum steel. I. D. Pichakhchi. Metallurg. No. 9, 45-54 (1959). — Elec. furnace steels contg. (1) C 0.33, Cr 0.54, Ni 2.76 and Mo 0.40% and (2) C 0.33, Cr 0.73, Ni 2.90 and Mo 0.40% were studied. (1) was deoxidized with ferro-manganese and ferro-silicon immediately after removal of the oxidizing slag, by use of moist lime to form slag; (2) was held under a carbide slag before deoxidation and dry lime was added to form slag. Both steels were forged into billets 220 mm. in diam. and subjected to various heat-treatments. When cooled in air after forging, (1) was very sensitive to flake formation while (2) was not. Flakes could be avoided in (1) by cooling the steel after forging in air to 200-480° and then transferring to a furnace at 600° and holding for 3-5 hrs.; thus H was permitted to diffuse from the steel.

during the interaction of a traveling magnetic field with the flow of ionized
gasSOURCE: Magnitnaya gidrodinamika, no. 2, 1965, 67-79

TOPIC TAGS: MHD flow, transmission line, traveling wave interaction

ABSTRACT: Study of the interaction between the plasma stream and the transverse magnetic field of the traveling wave moving in an artificial transmission line theory with localized inductances and capacities is reported. Transmission line theory is adapted with proper simplifications to computation of amplification coefficient, useful power delivered to a resistive load, electrical efficiency and the magnitude of the positive feedback occurring in the self-excitation regime. Both leakage flux and finite ratio of channel width to the characteristic wavelength are taken into account. The computational results were checked with the experi-

AUTHOR: Pichakhchi, L.D.

TITLE: Discontinuities in a rarefied plasma in the Chew-Goldberger-Low approximation

PERIODICAL: Ukravins'kyy fizychnyy zhurnal, v. 5, no. 4, 1960,
450-457

TEXT: The discontinuities of a rarefied plasma are classified in accordance with the Chew-Goldberger-Low equations. In the Chew-Goldberger-Low approximation, a rarefied plasma is described by

$$\rho \frac{\partial v_i}{\partial t} + \rho v_k \frac{\partial v_i}{\partial x_k} = - \frac{\gamma_{ik}}{\partial x_k} - \frac{1}{4\pi} H_k \frac{\partial H_k}{\partial x_i} + \frac{1}{4\pi} E_k \frac{\partial E_k}{\partial x_k} \quad (1)$$

The continuity equations are set up, whereby

$$\Pi_{ik} = \rho v_i v_k + p_{ik} - \frac{1}{4\pi} \left[H_i H_k - \frac{1}{2} \delta_{ik} H^2 \right]; \quad (2)$$

Card 1/5

27945

S/185/60/005/004/003/021

Discontinuities in a rarefied plasma... D274/D306

The conditions which hold on the discontinuity surface are

$$\{j\} = \{\rho v_n\} = \left\{ \frac{v_n}{V} \right\} = 0 \quad (13)$$

$$\{H_n\} = 0; \quad (14)$$

$$\{E_t\} = H_n \{v_t\} - j \{V H_t\} = 0; \quad (15)$$

$$\{Q_n\} = j \left\{ \frac{v_t^2}{2} + \frac{1}{2} j^2 V^2 + \frac{5}{2} p_{\perp} V + \frac{1}{2} a V + \frac{1}{4\pi} V H_t^2 + \frac{H_n^2}{H^2} a V \right\} - \\ - \frac{H_n}{4\pi} \left\{ H_t v_t \left(1 - 4\pi \frac{a}{H^2} \right) \right\} = 0 \quad (16)$$

(where $a = p_{||} - p_{\perp}$), and the conditions

$$j^2(V) + \{p_{\perp}\} + H_n^2 \left\{ \frac{a}{H^2} \right\} + \frac{1}{8\pi} \{H_t^2\} = 0; \quad (17)$$

$$j \{v_t\} + H_n \left\{ H_t \frac{a}{H^2} \right\} - \frac{H_n}{4\pi} \{H_t\} = 0. \quad (18)$$

Card 2/5

2745
3/185/60/005/004/003/021
Discontinuities in a rarefied plasma... D274/D306

city are the same on each side of the discontinuity surface, in addition, if $H_n = 0$, then all the quantities are continuous and there is no discontinuity; hence the importance attached to the conditions $H_n \neq 0$. A system of equations is obtained which includes

$$\left\{ \left[j^* V - \frac{H_n^2}{4\pi} \left(1 - 4\pi \frac{a}{H^2} \right) \right] H_t \right\} = 0; \quad (31)$$

Eq. (31) yields two possibilities. The first one involves (as a particular case), a rotational discontinuity: the magnetic field H_t and the velocity v_t rotate in the discontinuity surface by an arbitrary angle. In the second case, Eq. (31) is a scalar equation. Both j and $\{\rho\}$ are different from zero. The velocity of the plasma is different on each side of the discontinuity surface. The general case is considered: $H_n \neq 0$. Equations are derived, one of which involves an arbitrary jump of H_t , and another determines the velocity of propagation of the discontinuity

$$-u_i = v_{in} = \frac{H_n}{\sqrt{4\pi\rho}} \sqrt{1 - 4\pi \frac{a_i}{H_t^2}}, \quad i = 1, 2, \quad (52)$$

TITLE: The effect of busbars on the current interaction of conducting fluid flow with the traveling wave magnetic field

SOURCE: Magnitnaya gidrodinamika, no. 1, 1966, 109-115

TOPIC TAGS: electroconductive fluid, electromagnetic field, magnetic effect, traveling wave, wave function, traveling wave interaction, electric inductance

ABSTRACT: An analysis has been made of the effect of electroconducting busbars on the current interaction of conducting fluid flow with the traveling wave magnetic field created by a long line of concentrated inductances and capacitances. An expression for the amplification coefficient as a function of the ratio of busbar thickness and duct width to the wavelength was obtained. The inclusion of busbars increases the amplification coefficient. Orig. art. has: 4 figures and 22 formulae. [Based on authors' abstract]

TITLE: Contribution to the theory of the hydromagnetic dynamo

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 50, no. 3, 1966, 818-820

TOPIC TAGS: magnetohydrodynamics, hydromagnetics, electric field, magnetic field

ABSTRACT: The Cowling theorem of magnetohydrodynamics, which states that a stationary axially symmetrical hydromagnetic dynamo is impossible, is extended to include an arbitrary three-dimensional case. From this expanded proof, which is based on an analysis of the kinematic equations of a hydromagnetic dynamo with zero field and the boundary conditions in the dynamo, it follows that when a magnetic field is generated in the stationary case, the electric charges must be separated in the liquid, so that an electric field must be produced in space in addition to the magnetic field. The author is grateful to M. A. Gol'dshtik for a discussion of the work. Orig. art. has: 11 formulas.

(Ref. 1: Elektrodinamika sploshnykh sred (Electro-dynamics of continuous media) GITTL, M. 1957). Two groups of waves arise: Alfvén waves and magneto-acoustic waves. If in the first-order approximation either of the group of waves propagates, the system of equations (1.10-1.12) reduces to:

$$\frac{\partial^2 v_{zx}}{\partial t^2} - \left(c^2 + \frac{H_x^2}{4\pi\rho} \right) \frac{\partial^2 v_{zx}}{\partial x^2} + \frac{H_x j H_y}{4\pi\rho} \frac{\partial^2 v_{zy}}{\partial x^2} = f(x, t), \quad (1.16)$$

$$\frac{\partial^2 v_{zy}}{\partial t^2} - u_z^2 \frac{\partial^2 v_{zy}}{\partial x^2} + \frac{H_x H_y}{4\pi\rho} \frac{\partial^2 v_{zx}}{\partial x^2} = \varphi(x, t), \quad (1.17)$$

$$\text{where } \frac{\partial^2 v_{zz}}{\partial t^2} - u_z^2 \frac{\partial^2 v_{zz}}{\partial x^2} = \psi(x, t), \quad (1.18) \quad \times$$

$$f(x, t) = -\frac{1}{4\pi\rho} \frac{\partial}{\partial t} \left(H_{12} \frac{\partial H_{12}}{\partial x} \right), \quad \varphi(x, t) = 0, \quad \psi(x, t) = 0 \quad (1.19)$$

for the Alfvén wave and

Card 3/6

Magnetohydrodynamic waves...

S/185/61/006/003/002/010
D208/D302

$$\begin{aligned} f(x, t) = & -\frac{\partial}{\partial t} \left(\frac{\rho_1}{\rho} \frac{\partial v_{1x}}{\partial t} + v_{1x} \frac{\partial r_{1x}}{\partial x} + \frac{H_{1y}}{4\pi\rho} \frac{\partial H_{1y}}{\partial x} - \frac{c}{\rho} \frac{dc}{d\rho} \frac{\partial \rho^2}{\partial x} \right) - \\ & - \frac{\partial^2}{\partial x^2} \left(\frac{c^2}{\rho} \rho_1 r_{1x} + \frac{H_y}{4\pi\rho} v_{1x} H_{1y} \right), \end{aligned} \quad (1.20)$$

$$\varphi(x, t) = -\frac{\partial}{\partial t} \left(\frac{\rho_1}{\rho} \frac{\partial v_{1y}}{\partial t} + v_{1x} \frac{\partial r_{1y}}{\partial x} \right) - \frac{H_x}{4\pi\rho} \frac{\partial^2}{\partial x^2} (v_{1x} H_{1y}), \quad \psi(x, t) = 0$$

for the magneto-acoustic wave. After some transformations one obtains for the Alfvén wave the solution X

$$\beta_2 = 0, \quad H_{2y} = -\frac{h^2}{2H_y} \cos 2k(x - u_1 t), \quad v_{2y} = -\frac{H_x}{4\pi\rho u_1} h_{2y}. \quad (1.29)$$

Hence in the second-order approximation an Alfvén wave arises with double frequency and plane of oscillation perpendicular to that of the first-order wave. The magneto-acoustic wave which arises has harmonics. If in the first-order approximation both the Alfvén and magneto-acoustic waves propagate, the solution has the form

$$v_{2x} = \frac{\alpha\gamma}{2u_2} \left\{ 1 - \cos k(u_2 - u_1)t + \frac{u_2^2 - u_1^2 + 2u_1u_2}{(3u_1 + u_2)(u_1 - u_2)} \cos 2k \left(x - \frac{u_1 + u_2}{2}t \right) - \right. \\ \left. - \frac{u_2^2 - u_1^2 + 2u_1u_2}{4u_1} \left[\frac{1}{3u_1 + u_2} \cos 2k(x + u_1t) + \frac{1}{u_1 - u_2} \cos 2k(x - u_1t) \right] \right\} + (1.37)$$

an analogous term in which λ is replaced by β , and u_2 by u_3 . A peculiar feature of this solution is the aperiodic term which might be interpreted as a "wave wind". Further computations, which are not given in their entirety, lead to waves of unchanging amplitude with a velocity not only depending on u_2 and u_3 , but also on u_1 : X

another harmonic which has an amplitude proportional with time, also appears. The magnetohydrodynamics equations in the approximation of G.F. Chew, M.L. Goldberger and F.S. Low are also considered (Ref. 7: Proc. Roy. Soc. A 236, 112, 1956). The reasoning applied to these equations is similar to the foregoing. The conclusions reached are also similar, with the sole difference that the expressions for the amplitudes are more cumbersome. The author thanks

TITLE: Atomic Hydrogen Emission Excited by Synchrotron
Radiation Due to Relativistic Electrons

PERIODICAL: Astronomicheskiy zhurnal, 1961, Vol. 38, No. 1
pp. 87 - 90

TEXT: The first of the present authors has shown (Refs. 1 - 2) that the principal features of the emission spectra of late spectral class dwarfs, giving rise to ultraviolet radiation can be explained by assuming that they are excited by high intensity synchrotron radiation in a relatively small portion of the atmosphere of the star, i.e. its active zone. It was suggested that the ionisation of hydrogen is due to the ultraviolet part of the spectrum of the synchrotron radiation, while the infrared part is due to induced transitions from the continuum to the upper energy levels. This leads to an increase in the population of the upper levels and the associated anomalies in the Balmer decrement, as well as the broadening and blending of higher members of the Balmer series

forming the so-called Balmer quasi-continuum. Furthermore
a method was put forward in Refs. 1 and 2 which can be used
to determine the spectrum of the synchrotron emission from
the observed hydrogen emission spectrum. The aim of the
present work is to compute the distribution of hydrogen atoms
over excited states in the field of synchrotron radiation
whose spectrum is of the form:

$$I_V = A \cdot V^{-\alpha} \quad (1)$$

where $\alpha = 1/2$ and $A = 1.65 \times 10^7$ (Gordon - Ref. 2). It is
assumed that the electrons obey a Maxwell velocity distribution
and that the synchrotron radiation spectrum is cut off on the
low-frequency side in accordance with the condition:

$$I_V = 0, \quad V < V_{\min} = 0.57 \times 10^{13} \text{ c p s. } (3)$$

Calculations have shown that all the induced transitions for $m > n$ are forbidden if $n \geq 23$. The problem has been solved numerically with the aid of the electronic computer "Ypañ" ("Ural") of the Laboratory of Computational Mathematics of Khar'kovskiy gosudarstvennyy universitet (Khar'kov State University). The numerical results obtained for $a = 0.56$ and $T_e = 5\ 000^\circ K$ are summarised in the table on p. 89. The first column gives the level number, the second gives the values of b_n^* indicating the factor by which the population of the given level differs from the population in thermodynamic equilibrium at $T_e = 5\ 000^\circ K$ and the third column gives the quantity b_n^* which is a measure of the level population. Fig. 1 gives $\log b_n^*$ (lower curve) and b_n^* (upper curve) as a function of n for hydrogen atoms in the

field of synchrotron radiation in the active zone of a T Tau type star with anomalous emission in the ultraviolet. A consideration of the table and figure shows that a minimum occurs at $n = 2$ as a result of which all the Balmer series lines should appear as negative absorption lines. It is noticeable that the monotinoc increase in the population is reversed at about $n = 15$, which is due to the cut-off applied to the synchrotron emission spectrum on the low-frequency side. The Paschen series will also be observed as a series of negative absorption lines, since the population of the third level, although greater than that of the second level is nevertheless lower than the population of higher levels. The striking feature of the distribution is the over-population of the upper levels. This was predicted by the first of the present authors in Ref. 1 and leads to the appearance of a Balmer quasi-continuum in the emission spectra of the active zone. Calculations show that the rapid increase in the

to Relativistic Electrons

Population of the upper levels masks the reduction in the absorption coefficient, as a result of which the intensity in the quasi-continuum increases towards the Balmer limit, which is in agreement with spectrophotometric data for stars with anomalous ultraviolet emission. It is known that the majority of T Tau type stars do not exhibit the anomalous emission in the ultraviolet and their spectra contain only the discrete hydrogen emission lines. It is suggested that the emission spectra of this type are excited by synchrotron radiation with a less intense infra-red region. This problem will be considered in a further paper. TITLE
An automatic device for potentiometric titration
PERIODICITY
1961

REVIEWER
The variations of the potential were worked out, which make it convenient to carry out laboratory potentiometric titrations. An automatic device for potentiometric determinations permit automation of titrations up to a certain potential value. Titration is carried out up to a certain potential value, so that it is possible to compare various electrode combinations and titration methods. The method for different methods of titrations and titration curves is based on the potential of the equivalent point. It is either measured directly from the titration point or it is calculated. In the scheme (fig 1) of the titration apparatus the potential difference between the two electrodes of the titration cell are arranged in series and connected to an amplifier, so that the difference of potential is fed to the amplifier, from where it goes to a relay system (after the amplifier, titration is stopped), while an indicator voltmeter is connected in parallel. During the course of the titration

Card 1/3

An Automatic Device for Potentiometric Titration

0576
SOV/32-25-10-49-1

be followed visually. For the protection of the voltmeter from being overloaded, a diode stopping device is connected in parallel to the measuring instrument. By means of the relay system, which contains a cascade amplifier and a switch, the connection between the reagent and the titration cell is interrupted at such a time when equivalence point is reached, i.e. titration is ended. The basic scheme of the device (Fig. 1) shows that an infrared photovoltaic meter of the type A-4, i.e. diode stopping device with germanium diodes of the type 1N34A, as well as germanium diodes of the type DGTs-27 are used. Various titration variants are described and the results obtained are presented (Table). In the case of the second variety (Fig. 3) the scheme the titration liquid is, after adjustment of a timer to "titration", then automatically introduced slowly into the cell by means of a servo-mechanism and near the equivalence point more slowly. The end of titration is indicated by means of a bell signal. This variant contains an internal and an external potentiometer, the titration cell, and a breaker, from which the voltage is supplied over a voltage amplifier to a thyratron with 2 relays. The operation of the device as well as a wiring scheme (Fig. 3)

TITLE: On the Problem of the Polarization of Light in the Emission Lines of Unsteady Stars Excited by a Stream from Relativistic Electrons (K voprosu o polarizatsii sveta v emisiiakh nestatsionarnykh zvezd, vvertivayushchikh sinhrotronnym izlucheniem relativistskikh sverktronov)

PERIODICAL: Dokl. by Akad. Nauk SSSR, 105, Vol. 120, Nr. 1, pp. 55 - 58 (USSR)

ABSTRACT: The aim of the present paper is the calculation of the depolarization of the emission lines of hydrogen occurring on various conditions of scattering of a linearly polarized electron radiation at excited hydrogen atoms. This calculation also holds for other atoms similar to hydrogen. The polarization properties of the light scattered at excited atoms was investigated by V.L.German (Ref. 4). The same author gives a formula for the probability of the scattering of light. The author investigates the case where the excited state of the hydrogen atom occurs in consequence of the absorption of the linearly polarized light; the corresponding formula for the probability of scattering of light is given and transformed for the reason of simplification.

Card 1/3

On the Problem of the Polarization of Light in the
Emission Lines of Unsteady States Excited by a Scattered Beam of
Relativistic Electrons

tion. An expression is also written down for the depolarization coefficient corresponding to this case. The minimum depolarization coefficient has the value 7% at $\alpha = \pi/2$. Then the author derives the formulae for the scattering probability for the following cases: The excited state occurs at the transition of the electron from the continuous spectrum to the second level; the excitation is caused by unpolarized light, and the polarized radiation in the line H_{α} is scattered; the excitation takes place under the influence of a linearly polarized light, so that unpolarized light is scattered. The latter case could be of interest for the theory of the spectra of unsteady states. In this case the minimum depolarization coefficient is 75%. Correspondingly the minimum polarization in the line H_{α} excited by the scattering of natural light on hydrogen atoms (and by linearly polarized light) is 25%. The formulae derived for the depolarization coefficient of the line H_{α} maintain their form also for the corresponding cases of the radiation of other

Card 2/3

On the Problem of the Polarization of Light in the Emission Lines of Unsteady Stars Excited by a Synchrotron Radiation of Relativistic Electrons

lines of the Balmer series with the only difference that other radial integrals enter the expression for the scattering matrix. The depolarization of the scattered light depends only on the symmetry of the state of the scattering atom and not on the frequency of the scattered light. Immediate observations of the Lyman lines and of the Lyman continuum of the spectra of unsteady stars are not possible at present as such observations have to be made outside the earth's atmosphere. There are 7 references, 6 of which are Soviet.
